

# Applications of IUT Theory to Diophantine Geometry and Equations over the rational numbers

Zhong-Peng Zhou

ITS, Westlake University

March 20, 2025

# Introduction

In this talk, we explore the applications of Inter-universal Teichmüller (IUT) theory to two Diophantine problems:

- The effective abc inequalities over  $\mathbb{Q}$
- The generalized Fermat equations

# References

## Effective abc inequalities, cf. [ExpEst]

In [IUTchIV], Mochizuki verified various *numerically non-effective* versions of the Vojta, ABC, and Szpiro Conjectures over number fields.

In [ExpEst], Mochizuki-Fesenko-Hoshi-Minamide-Porowski obtained various *numerically effective* versions of Mochizuki's results over  $\mathbb{Q}$  and imaginary quadratic fields. For the case of  $\mathbb{Q}$ , they proved:

### Theorem (Effective version of a conjecture of Szpiro)

Let  $a, b, c$  be non-zero coprime integers such that  $a + b + c = 0$ ;  $\epsilon$  a positive real number  $\leq 1$ . Then we have

$$|abc| \leq 2^4 \cdot \max\{\exp(1.7 \cdot 10^{30}) \cdot \epsilon^{-166/81}, \text{rad}(abc)^{3+3\epsilon}\}.$$

# Effective abc inequalities (2)

## Corollary 1

Fermat's Last Theorem (FLT) holds for prime exponents  $> 1.615 \cdot 10^{14}$ .

This work, combined with the results of Vandiver, Coppersmith, and Mihăilescu-Rassias, yields an **unconditional new alternative proof** of Fermat's Last Theorem (FLT).

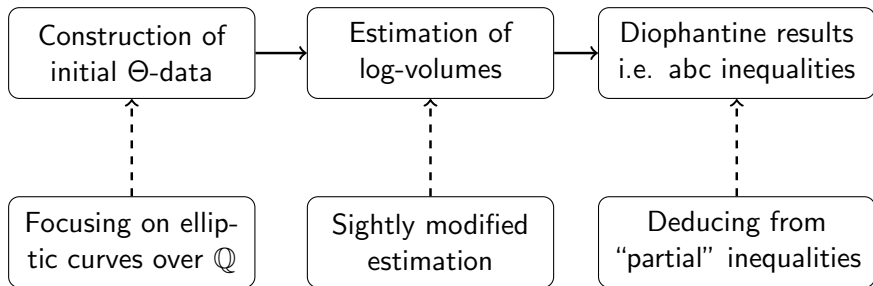

## Corollary 2

When  $r, s, t > 2.453 \cdot 10^{30}$ , the generalized Fermat equation  $x^r + y^s = z^t$  has no positive coprime integer solution.

**Question:** Can we prove stronger abc inequalities, and prove stronger results towards the generalized Fermat equations?

# Applications of IUT to effective abc ineqs., cf. [IUT-Q-I]

## Flowchart:

## Construction of initial $\Theta$ -data, cf. [IUT-Q-I], §2

As defined in [IUTchIV] and [ExpEst], a  $\mu_6$ -initial  $\Theta$ -data  $(\bar{F}/F, X_F, \ell, \underline{C}_K, \underline{V}, \mathbb{V}_{\text{mod}}^{\text{bad}}, \underline{\epsilon})$  consists of the following objects:

- An elliptic curve  $E_F$  over a number field  $F$ ; denote  $X_F = E_F \setminus \{O\}$ ,  $F_{\text{mod}} = \mathbb{Q}(j(E_F))$ , assume  $F/F_{\text{mod}}$  is Galois and  $F(\sqrt{-1}, E_F[6]) = F$ .
- A prime number  $\ell \geq 5$ , s.t.  $\ell \nmid [F : F_{\text{mod}}]$ ; Denote  $K = F(E_F[\ell])$ , and assume that the image of the mod  $\ell$  Galois repr. of  $E_F$

$$\rho_{E_F, \ell} : G_F \twoheadrightarrow \text{Gal}(F(E_F[\ell])/F) \rightarrow \text{Aut}(E_F[\ell]) \cong \text{GL}(2, \mathbb{F}_\ell)$$

contains the subgroup  $\text{SL}(2, \mathbb{F}_\ell) \subseteq \text{GL}(2, \mathbb{F}_\ell)$ .

- A non-empty collection of “bad” valuations  $\mathbb{V}_{\text{mod}}^{\text{bad}} \subseteq \mathbb{V}_{\text{mod}}$ .
- A curve  $\underline{C}_K$  with  $K$ -core  $C_K = X_K / \{\pm 1\}$ , where  $X_K = X_F \times_F K$ .
- A section  $\eta : \mathbb{V}_{\text{mod}} \xrightarrow{\sim} \underline{V} \subseteq \mathbb{V}(K)$  of  $\mathbb{V}(K) \rightarrow \mathbb{V}_{\text{mod}}$ .

There are some more definitions and assumptions.

## Construction of initial $\Theta$ -data (2)

**Notations.** For a  $\mu_6$ -initial  $\Theta$ -data

$$\mathfrak{D} = (\overline{F}/F, X_F, \ell, \underline{C}_K, \underline{\mathbb{V}}, \mathbb{V}_{\text{mod}}^{\text{bad}}, \underline{\epsilon})$$

with  $F_{\text{mod}} = \mathbb{Q}$ , let  $N$  be the denominator of the  $j$ -invariant  $j(E_F) \in \mathbb{Q}$ , and let  $N'$  be the maximal divisor of  $N$  whose prime divisors corresponds to places in  $\mathbb{V}_{\text{mod}}^{\text{bad}}$ , i.e.

$$N' := \prod_{p: v_p \in \mathbb{V}_{\text{mod}}^{\text{bad}}} p^{v_p(N)}.$$

Then we have  $\log(N') = \log(q)$  in the notation of [IUTchIV], Theorem 1.10. We shall say  $\mathfrak{D}$  is **of type**  $(\ell, \mathbf{N}, \mathbf{N}')$ .

## Construction of initial $\Theta$ -data (3)

### Proposition

Let  $E$  be an elliptic curve defined over  $\mathbb{Q}$ ;  $N$  be the denominator of  $j(E)$ ;  $F$  be a number field Galois over  $\mathbb{Q}$ ;  $\ell \geq 11$  be a prime number such that  $\ell \nmid [F : \mathbb{Q}]$ ;  $E_F := E \times_{\mathbb{Q}} F$ ,  $X_F = E_F \setminus \{O\}$ . Suppose that:

- (1)  $\sqrt{-1} \in F$ ,  $F(E[6]) = F$ ,  $E_F$  is semi-stable, and  $F \subseteq \mathbb{Q}(E[n])$  for some positive integer  $\ell \nmid n$ .
- (2)  $j(E) \notin \{0, 2^6 \cdot 3^3, 2^2 \cdot 73^3 \cdot 3^{-4}, 2^{14} \cdot 31^3 \cdot 5^{-3}\}$ .
- (3) We have  $\ell \neq 13$  and  $N$  is not a power of 2; or  $E$  is semi-stable.
- (4) We have  $N'_\ell \neq 1$ , where  $N'_\ell := \prod_{p: p \neq \ell, \ell \nmid v_p(N)} p^{v_p(N)}$ .

Then there exists a  $\mu_6$ -initial  $\Theta$ -data  $\mathfrak{D} = (\overline{F}/F, X_F, \ell, \underline{C}_K, \underline{\mathbb{V}}, \mathbb{V}_{\text{mod}}^{\text{bad}}, \underline{\epsilon})$ , which is of type  $(\ell, N, N'_\ell)$ .

## Construction of initial $\Theta$ -data (4)

**Remark.** In the previous proposition:

- (1)  $\Rightarrow$  the image of the mod  $\ell$  repr.  $\rho_{E_F, \ell}$  of  $E_F$  equals that of  $E$ .
- (3), (4)  $\Rightarrow$  the mod  $\ell$  repr.  $\rho_{E, \ell}$  of  $E$  is surjective, cf. Mazur, “Rational isogenies of prime degree (with an appendix by D. Goldfeld)”,
- (2)  $\Rightarrow C_K$  is the  $K$ -core of  $\underline{C}_K$  and  $X_K$ , cf. [ExpEst], Proposition 2.1, also cf. Sijsling, “Canonical models of arithmetic  $(1; e)$ -curves”.
- (4)  $\Rightarrow \mathbb{V}_{\text{mod}}^{\text{bad}} \neq \emptyset$ .
- If the image of  $\rho_{E, \ell}$  contains  $\text{SL}(2, \mathbb{F}_\ell)$ , then  $\exists$  suitable  $\underline{C}_K, \underline{\mathbb{V}}, \underline{\epsilon}$ , which constitute a  $\mu_6$ -initial  $\Theta$ -data  $(\overline{F}/F, X_F, \ell, \underline{C}_K, \underline{\mathbb{V}}, \mathbb{V}_{\text{mod}}^{\text{bad}}, \underline{\epsilon})$ .
- $v_p \notin \mathbb{V}_{\text{mod}}$  if and only if  $p = \ell$  or  $\ell \mid v_p(N)$ , hence “ $N' = N'_\ell$ ”.

## The $\mu_6$ -initial $\Theta$ -data associated to “ $a + b = c$ ”

Let  $(a, b, c)$  be a triple of non-zero coprime integers such that  $a + b = c$ .

Let  $\ell \geq 11$ ,  $\ell \neq 13$  be a prime number, cf. (3).

Let  $N = a^2 b^2 c^2 / \gcd(2^8, a^2 b^2 c^2)$ ,  $N'_\ell = \prod_{p: p \neq \ell, \ell \nmid v_p(N)} p^{v_p(N)}$ .

Suppose that:

- $(|a|, |b|, |c|)$  is not a permutation of  $(1, 1, 2)$ ,  $(1, 8, 9)$ , cf. (2).
- $N'_\ell \neq 1$ , cf. (4).

Let  $E$  be the Frey-Hellegouarch curve associated to  $(a, b, c)$ , which is defined over  $\mathbb{Q}$  by the equation  $y^2 = x(x - a)(x + b)$ .

## The $\mu_6$ -initial $\Theta$ -data associated to “ $a + b = c$ ” (2)

Write  $F = \mathbb{Q}(\sqrt{-1}, E[3])$ , then:

- $N$  is the denominator of  $j(E) = 256(a^2 + ab + b^2)^3 / a^2 b^2 c^2$ .
- $F$  is Galois over  $\mathbb{Q}$ ,  $\sqrt{-1} \in F$ ,  $F(E[6]) = F$ ,  $E_F$  is semi-stable, and  $F \subseteq \mathbb{Q}(E[12])$ , cf. (1).

Thus, based on the previous proposition  $\Rightarrow$

There exists a  $\mu_6$ -initial  $\Theta$ -data

$$\mathfrak{D}(E, F, \ell, \mu_6) = (\overline{F}/F, X_F, \ell, \underline{C}_K, \underline{\mathbb{V}}, \mathbb{V}_{\text{mod}}^{\text{bad}}, \underline{\epsilon}),$$

which is **of type**  $(\ell, N, N'_\ell)$ .

# Estimation of log-volumes, cf. [IUT-Q-I], §1

In this part, we shall make use of [IUTchIII], Corollary 3.12 and its  $\mu_6$ -version in [ExpEst], which play key roles in the application in [IUT-Q-I] and [IUT-Q-II]. The proofs of them relies on strong anabelian geometry results primarily established by Mochizuki.

Theorem (cf. [IUTchIV], [ExpEst])

$$-|\log(\underline{\underline{q}})| \leq -|\log(\underline{\underline{\Theta}})|$$

By estimating  $-|\log(\underline{\underline{\Theta}})|$ , we can obtain upper bounds for  $-|\log(\underline{\underline{q}})|$ .

# Estimation of log-volumes (2)

## Notations.

Let  $\mathfrak{D} = (\overline{F}/F, X_F, \ell, \underline{C}_K, \underline{V}, \mathbb{V}_{\text{mod}}^{\text{bad}}, \underline{\epsilon})$  be a  $\mu_6$ -initial  $\Theta$ -data, such that  $F_{\text{mod}} = \mathbb{Q}$ . Let  $N$  be the denominator of  $j(E_F)$ . Suppose that  $\mathfrak{D}$  is of type  $(\ell, N, N')$ .

For each  $v_p \in \mathbb{V}_{\mathbb{Q}}^{\text{non}}$ , let  $\underline{v}_p := \eta(v_p) \in \underline{V} \subseteq \mathbb{V}(K)^{\text{non}}$ . Write  $e_p$  for the **ramification index** of  $K_{\underline{v}_p}$  over  $\mathbb{Q}_p$ ; write  $d_p \in \frac{1}{e_p} \cdot \mathbb{Z}$  for the **different index** of  $K_{\underline{v}_p}$ , i.e. the  $p$ -adic valuation of any generator of the different ideal of the ring of integers of  $K_{\underline{v}_p}$  over  $\mathbb{Z}_p$ .

We have  $d_p = 0$  when  $e_p = 1$ ;  $d_p = 1 - \frac{1}{e_p}$  when  $p \nmid e_p$ ;  $d_p \leq 1 + v_p(e_p)$  when  $p \mid e_p$  [cf. [IUTvhIV], Proposition 1.3].

## Estimation of log-volumes (3)

### Proposition

$$\begin{aligned} \frac{1}{6} \log(N') \leq & \frac{\ell^2 + 5\ell}{\ell^2 + \ell - 12} \cdot \left( \log(\pi) + \sum_{e_p \geq p-1} \left( \frac{1}{p-1} + 1 - \frac{p-1}{e_p} \right) \cdot \log(p) \right. \\ & \left. + \sum_{p \geq 2} d_p \cdot \log(p) + \sum_{e_p > p(p-1)} \log\left(\frac{e_p}{p-1}\right) \right). \end{aligned}$$

**Remark.** In [IUTchIV] and [ExpEst], the inequality  $e_p \leq [K : \mathbb{Q}]$  is used to get an upper bound of the RHS of the inequality in the above proposition. However, for special classes of elliptic curves, one may prove smaller upper bounds for  $e_p$ .

## Partial abc inequalities, cf. [IUT-Q-I], §2

**Example for the  $\mu_6$ -initial  $\Theta$ -data associated to “ $a + b = c$ ”.**

- For  $p \neq 2, 3, \ell$ , if  $p \mid abc$ , then  $e_p \mid 3\ell$ ,  $d_p = 1 - \frac{1}{e_p} \leq 1 - \frac{1}{3\ell}$ ; if  $p \nmid abc$ , then  $e_p = 1$ ,  $d_p = 0$ .
- For  $p \in \{3, \ell\}$ , if  $p \mid abc$ , then  $e_p \in (p-1) \cdot \{1, 3, \ell, 3\ell\}$ ,  $d_p \leq 2$ ; if  $p \nmid abc$ , then  $e_p \in \{p-1, p(p-1), p^2-1\}$ ,  $d_p \leq 2$ .
- For  $p = 2$ , if  $v_2(abc) \geq 5$ , then  $e_2 \in \{2, 6, 2\ell, 6\ell\}$ ,  $d_2 \leq 2$ ; if  $1 \leq v_2(abc) \leq 4$ , then  $2 \mid e_2$ ,  $e_2 \mid 48$  and  $d_2 \leq 1 + v_2(e_2) \leq 5$ .

## Partial abc inequalities (2)

### Proposition (Partial abc inequality)

Let  $(a, b, c)$  be a triple of non-zero coprime integers such that  $a + b = c$ , let  $\ell \geq 11$  be a prime number s.t.  $\ell \neq 13$ , let  $N = |abc|/\gcd(16, abc)$ .

Then there exists a real number  $\text{Vol}(\ell) \geq 0$  [which only depends on  $\ell$ ], s.t.

$$\log\left(\prod_{p:p \neq \ell, \ell \nmid v_p(N)} p^{v_p(N)}\right) \leq \left(3 + \frac{11\ell + 31}{\ell^2 + \ell - 12}\right) \cdot \log \text{rad}(N) + 3 \text{Vol}(\ell).$$

Here we have  $\text{Vol}(\ell) < \frac{3}{2} \cdot \ell + 0.06 \cdot \frac{\ell}{\log(\ell)}$  for  $\ell \geq 2 \cdot 10^5$ .

## Effective abc inequaties, cf. [IUT-Q-I], §3

Rather than  $\log(N)$ , the left hand of the partial abc inequality equals

$$\log\left(\prod_{p:p \neq \ell, \ell \nmid v_p(N)} p^{v_p(N)}\right) = \log(N) - \underbrace{\sum_{p: p=\ell \text{ or } \ell \mid v_p(N)} v_p(N) \cdot \log(p)}_{\text{the error term at } \ell},$$

which depends on  $\ell$ . This is why it is called “partial abc inequality”.

**Question: How to deduce effective abc inequaties from partial ones?**

In [IUT-Q-I], we control the error term by averaging the partial abc inequalities over a suitable finite set  $S$  of  $\ell$ .

# Effective abc inequaties (2)

## Theorem

Let  $(a, b, c)$  be a triple of non-zero coprime integers such that  $a + b = c$ . Suppose that  $\log(|abc|) \geq 700$ , then we have

$$\log(|abc|) \leq 3 \log \operatorname{rad}(abc) + 8 \sqrt{\log(|abc|) \cdot \log \log(|abc|)}.$$

## Corollary

Let  $(a, b, c)$  be a triple of non-zero coprime integers such that  $a + b = c$ ; let  $\epsilon$  be a positive real number  $\leq \frac{1}{10}$ . Then we have

$$|abc| \leq \max\{\exp(400 \cdot \epsilon^{-2} \cdot \log(\epsilon^{-1})), \operatorname{rad}(abc)^{3+3\epsilon}\}.$$

# Generalized Fermat equations

Let  $r, s, t \geq 2$  be positive integers. The equation

$$x^r + y^s = z^t, \text{ with } x, y, z \in \mathbb{Z}$$

is known as the **generalized Fermat equation** (GFE) with **signature**  $(r, s, t)$ .

A solution  $(x, y, z)$  to the generalized Fermat equation is called **non-trivial** if  $xyz \neq 0$ ; **positive** if  $x, y, z \in \mathbb{Z}_{\geq 1}$ ; and **primitive** if  $\gcd(x, y, z) = 1$ .

When  $\frac{1}{r} + \frac{1}{s} + \frac{1}{t} \leq 1$ , only the **Catalan solution**  $1^n + 2^3 = 3^2$  and the following **nine non-Catalan** solutions are currently known:

$$\begin{array}{lll} 2^5 + 7^2 = 3^4, & 17^7 + 76271^3 = 21063928^2, & 1414^3 + 2213459^2 = 65^7, \\ 7^3 + 13^2 = 2^9, & 9262^3 + 15312283^2 = 113^7, & 43^8 + 96222^3 = 30042907^2, \\ 2^7 + 17^3 = 71^2, & 3^5 + 11^4 = 122^2, & 33^8 + 1549034^2 = 15613^3. \end{array}$$

## Generalized Fermat equations (2)

In [IUT-Q-I, II], the following previously established results are used to excluded proven signatures.

The generalized Fermat equation  $x^r + y^s = z^t$  admits no non-trivial primitive solutions, except for the solutions potentially associated with the Catalan solutions and the nine non-Catalan solutions, when  $(r, s, t)$  is a **permutation** of:

- $(n, n, n), n \geq 3; (2, n, n), n \geq 4; (3, n, n), n \geq 3;$
- $(2, 3, n), n \in \{6, 7, 8, 9, 10, 15\}; (2, 4, n), n \geq 4; (2, 6, n), n \geq 3;$
- $(3, 3, n), 3 \leq n \leq 10^9; (3, 4, 5), (5, 5, 7), (5, 7, 7);$
- $(5, 5, q), \text{ prime } q \geq 11 > 3\sqrt{5 \log_2(5)}.$

**Catalan's conjecture** proven by Mihăilescu is also used in these two papers.

# Preliminary applications of IUT to GFE, cf. [IUT-Q-I], §4

## Flowchart:

## Theorem

For positive primitive solutions  $(x, y, z)$  to the generalized Fermat equation  $x^r + y^s = z^t$  ( $r, s, t \geq 3$ ), define  $h = \log(x^r y^s z^t)$ . Then we prove explicit upper bounds:

$$\begin{aligned} h &\leq 573 \quad (r, s, t \geq 8); \quad h \leq 907 \quad (r, s, t \geq 5); \quad h \leq 2283 \quad (r, s, t \geq 4); \\ h &\leq 14750 \quad (\min\{r, s\} \geq 4 \text{ or } t \geq 4); \quad h \leq 24626 \quad (r, s, t \geq 3). \end{aligned}$$

# Preliminary applications of IUT to GFE (2)

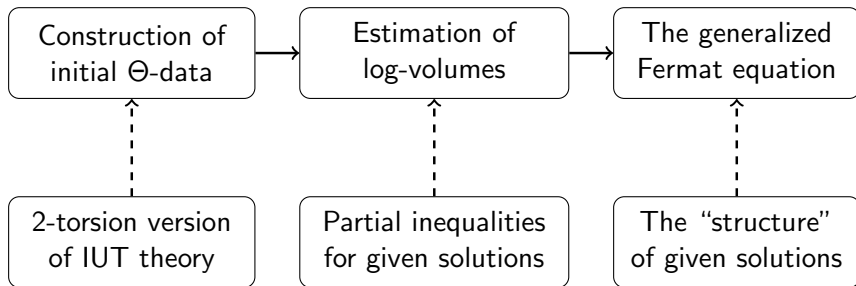

Some corollaries:

- (1) FLT holds for prime exponents  $\geq 11$ .
- (2) When  $r, s, t$  is a permutation of  $(3, 3, n)$  ( $n \geq 3$ ), the GFE  $x^r + y^s = z^t$  admits no non-trivial primitive solution.
- (3) When  $r, s, t \geq 20$ , the GFE  $x^r + y^s = z^t$  admits no non-trivial primitive solution.

**Question.** How to prove for smaller signatures/exponents  $(r, s, t)$ ?

# Refined applications of IUT to GFE, cf. [IUT-Q-II]

## Refined flowchart:

## 2-torsion version of IUT theory, cf. [IUT-Q-II], §1.1

**Definition.** We shall refer to **2-torsion initial  $\Theta$ -data** as any collection of data  $(\bar{F}/F, X_F, \ell, \underline{C}_K, \underline{V}, \mathbb{V}_{\text{mod}}^{\text{bad}}, \underline{\epsilon})$  satisfying the following conditions:

- The conditions in [IUTchl], Definition 3.1, (a), (c), (d), (e), (f).
- The “2-torsion version” of [IUTchl], Definition 3.1, (b), i.e., the condition obtained by replacing, in [IUTchl], Definition 3.1, (b), “2 · 3-torsion points of  $E_F$  are rational over  $F$ ”, by “2-torsion points of  $E_F$  are rational over  $F$ , and  $E_F$  has a model over  $F_{\text{mod}}$ ”.

### Comparison:

IUT version	About $\mathbb{V}_{\text{mod}}^{\text{bad}}$	About $F$
the original version	not dividing 2	$F(E_F[6], \sqrt{-1}) = F$
the $\mu_6$ -version	/	$F(E_F[6], \sqrt{-1}) = F$
the 2-torsion version	not dividing 2	$F(E_F[2], \sqrt{-1}) = F$ and $E_F$ has a model $E$ over $F_{\text{mod}}$

## 2-torsion version of IUT theory (2)

It is worth noting that the results of [IUTchI-IV] still hold for its 2-torsion version, i.e. by replacing initial  $\Theta$ -data with 2-torsion initial  $\Theta$ -data. In these papers, the condition “3-torsion points of  $E_F$  are rational over  $F$ ”, i.e. “ $F(E[3]) = F$ ” is only used in [IUTchI], Remark 3.1.5, [IUTchIV], Theorem 1.10 and [IUTchIV], Corollary 2.2 via [IUTchIV], Proposition 1.8, (iv), (v).

As a consequence of “ $F(E[3]) = F$ ”, it is stated that  $K$  is Galois over  $F_{\text{mod}}$  at the beginning of [IUTchI], Remark 3.1.5. This still holds for its 2-torsion version. Since  $E_F$  has a model  $E$  defined over  $F_{\text{mod}}$ , we can put  $L = F_{\text{mod}}(E[\ell])$ , then  $L/F_{\text{mod}}$  is Galois. Since  $F/F_{\text{mod}}$  is Galois by the definition of [2-torsion] initial  $\Theta$ -data, we can see that  $K = F(E_F[\ell]) = F \cdot L$  is Galois over  $F_{\text{mod}}$ .

## 2-torsion version of IUT theory (3)

The condition “ $F(E[3]) = F$ ” is also used to show that  $E_F$  has a model over  $F_{\text{mod}}$  in [IUTchIV], Theorem 1.10 and [IUTchIV], Corollary 2.2, after an initial  $\Theta$ -data is constructed. This is one of the conditions in the definition of 2-torsion initial  $\Theta$ -data.

Hence the results of [IUTchI-IV] (especially [IUTchIII], Corollary 3.12) **still hold** for their 2-torsion versions. The 2-torsion versions of “proposition for the construction of 2-torsion initial  $\Theta$ -data with  $F_{\text{mod}} = \mathbb{Q}$ ” and “partial inequalities” [which is based on the 2-torsion version of [IUTchIII], Corollary 3.12] can similarly be proven.

## Partial inequalities for solutions, cf. [IUT-Q-II], §2

Let  $r, s, t \geq 4$  be positive integers,  $(x, y, z)$  be a triple of positive coprime integers such that  $\delta_r x^r + \delta_s y^s = z^t$ , where  $\delta_r, \delta_s \in \{\pm 1\}$ . Let  $\ell \geq 11$  be a prime number.

Let  $(a, b, c)$  be a permutation of  $(\delta_r x^r, \delta_s y^s, -z^t)$ , such that  $4 \mid (a + 1)$  and  $16 \mid b$ . Then  $a + b + c = 0$ ,  $\gcd(a, b, c) = 1$ .

Let  $E$  be the elliptic curve defined over  $\mathbb{Q}$  by the equation

$$Y^2 + XY = X^3 + \frac{b - a - 1}{4} \cdot X^2 - \frac{ab}{16} \cdot X.$$

Then  $E$  is a semi-stable elliptic curve.

## Partial inequalities for solutions (2)

Let  $N = 2^{-8}x^{2r}y^{2s}z^{2t}$ , then  $N$  is the denominator of  $j(E)$ .

Let  $F = \mathbb{Q}(\sqrt{-1})$ ,  $E_F = E \times_{\mathbb{Q}} F$ .

Then there exists a 2-torsion initial  $\Theta$ -data  $\mathfrak{D} = \mathfrak{D}(E, F, \ell, 2\text{-tor})$  which is of type  $(\ell, N, N'_{2\ell})$ , where  $N'_{2\ell} = \prod_{p: p \nmid 2\ell, \ell \nmid v_p(N)} p^{v_p(N)}$ .

In this case, we have  $e_p = 1, d_p = 0$  or  $e_p = \ell, d_p = 1 - \frac{1}{\ell}$  for  $p \neq 2, \ell$ . By the estimation of log-volumes, for some real number  $\text{Vol}(\ell) \geq 0$ , we have the following partial inequality for solutions:

**Proposition (Partial inequality for given solutions)**

$$\frac{1}{3} \log \left( \prod_{p: p \nmid 2\ell, \ell \nmid v_p(x^r y^s z^t)} p^{v_p(x^r y^s z^t)} \right) \leq \frac{(\ell + 5)(\ell - 1)}{\ell^2 + \ell - 12} \cdot \sum_{p: \ell \nmid v_p(x^r y^s z^t)} \log(p) + \text{Vol}(\ell),$$

## Partial inequalities for solutions (3)

Let  $a_1(\ell) = 3 \cdot \frac{(\ell+5)(\ell-1)}{\ell^2+\ell-12}$ ,  $a_2(\ell) = 3 \cdot \text{Vol}(\ell) + a_1(\ell) \cdot \log(2\ell)$ .

Then  $3 < a_1(\ell) \leq 4$ ,  $a_2(11) \leq 71$ ,  $a_2(13) \leq 74$ , etc., and we have:

### Corollary

$$\sum_{p: p \nmid 2\ell, \ell \nmid v_p(x^r y^s z^t)} (v_p(x^r y^s z^t) - 4) \cdot \log(p) \leq a_2(\ell).$$

- Remark.** (1) To reduce “the number of possible solutions” to GFE in the subsequent steps, the smaller the values of  $\text{Vol}(\ell)$  and  $a_2(\ell)$ , the better.
- (2) These values depend on the values of various  $e_p$ , which is why we focus on the Frey-Hellegouarch curves and introduce a 2-torsion version of IUT theory.
- (3) Since  $r, s, t \geq 4$ , we can replace the LHS by its partial sum.

## Structure of solutions, cf. [IUT-Q-II], §2

Suppose that  $\ell \nmid r$  and consider the unique decomposition

$$x = x_1 \cdot 2^{r_2} \cdot \ell^{r_\ell} \cdot x_\ell^\ell, \quad \text{where } x_\ell = \prod_{p: p|2\ell, \ell|v_p(x)} p^{v_p(x)} \text{ and } \gcd(2\ell, x_1) = 1.$$

Then by the corollary, we have:

$$\log(x_1) - 4 \log \operatorname{rad}(x_1) \leq a_2(\ell).$$

Using the above inequality for different  $\ell$ , we can prove the following:

### Proposition

- (1) We have  $r \leq 313$ ,  $r_2 \leq \frac{306}{r}$ ,  $r_\ell \leq \frac{37}{r}$ .
- (2) We have  $x_\ell \in \{1, 3, 5\}$  if  $(r, \ell) = (4, 11)$ ;  $x_\ell \in \{1, 3\}$  if  $(r, \ell) = (4, 13), (4, 17), (5, 11), (5, 13), (6, 11)$ ; and  $x_\ell = 1$  otherwise.

## Structure of solutions (2)

Suppose that  $\ell \nmid rs$  and consider the similar unique decompositions

$$x = x_1 \cdot 2^{r_2} \cdot \ell^{r_\ell} \cdot x_\ell^\ell, \quad y = y_1 \cdot 2^{s_2} \cdot \ell^{s_\ell} \cdot y_\ell^\ell,$$

Then we have similar upper bounds for  $s, s_2, s_\ell, y_\ell$  by the proposition.

Meanwhile, by the corollary, we have

$$(r - 4) \log(x_1) + (s - 4) \log(y_1) \leq a_2(\ell).$$

Hence for each fixed signature  $(r, s, t)$ , there are only finitely many possible  $(x_1, y_1)$  and finitely many possible  $(r_2, s_2, r_\ell, s_\ell, x_\ell, y_\ell)$ , hence only **finitely many possible**  $(x, y)$ .

By checking whether  $|\pm x^r \pm y^s|$  is a  $t$ -th power for all possible  $(x, y)$ , we can find all positive coprime integers  $(x, y, z)$  satisfying  $\delta_r x^r + \delta_s y^s = z^t$ , where  $\delta_r, \delta_s \in \{\pm 1\}$ .

## Conclusions, cf. [IUT-Q-II]

After implementing the search algorithm, we have computed all signatures where  $r \leq s \leq t$  and  $r + s \geq 12$ , excluding those already solved:

### Proposition

For any integers  $r, s, t \geq 4$ , such that  $(r, s, t)$  is not a permutation of  $(4, 5, n), (4, 7, n), (5, 6, n)$  with  $7 \leq n \leq 301$ , the generalized Fermat equation

$$x^r + y^s = z^t$$

admits no non-trivial primitive solution.

**Remark.** By rough estimation, the search for signatures  $(4, 7, n), (5, 6, n)$  is computable [at least for large  $n$ ], but it needs at least hundreds of hours of wall clock time in total.

## Conclusions (2)

In [IUT-Q-II], the signatures  $(r, s, t)$  with  $\frac{1}{r} + \frac{1}{s} + \frac{1}{t} < 1$  are divided into four classes. Each class can be researched by using different classes of [modified] Frey-Hellegouarch curves:

Signatures Up To Permutations	Curves & Conditions
$r, s, t \geq 4$	$Y^2 + XY = X^3 + \frac{b-a-1}{4} \cdot X^2 - \frac{ab}{16} \cdot X,$ $a + b = c$ coprime, $4 \mid (a + 1)$ and $16 \mid b$
$(2, 3, t), t \geq 7$	$Y^2 = X^3 + 3bX + 2a, a^2 + b^3 = c$ coprime
$(3, r, s), r \geq 3, s \geq 4$	$Y^2 + 3cXY + aY = X^3, a + b = c^3$ coprime
$(2, r, s), r \geq 4, s \geq 5$	$Y^2 = X^3 + 2cX^2 + aX, a + b = c^2$ coprime

## Conclusions (3)

### Theorem

Let  $r, s, t \geq 2$  be positive integers such that  $\frac{1}{r} + \frac{1}{s} + \frac{1}{t} \leq 1$ . Then the generalized Fermat equation  $x^r + y^s = z^t$  admits no non-trivial primitive solution, except for the solutions related to the Catalan solutions  $1^n + 2^3 = 3^2$  and nine non-Catalan solutions, when  $(r, s, t)$  is not a permutation of the following signatures:

- $(4, 5, n)$ ,  $(4, 7, n)$ ,  $(5, 6, n)$ , with  $7 \leq n \leq 303$ .
- $(2, 3, n)$ ,  $(3, 4, n)$ ,  $(3, 8, n)$ ,  $(3, 10, n)$ , with  $11 \leq n \leq 109$  or  $n \in \{113, 121\}$ .
- $(3, 5, n)$ , with  $7 \leq n \leq 3677$ ;  $(3, 7, n)$ ,  $(3, 11, n)$ , with  $11 \leq n \leq 667$ .
- $(3, m, n)$ , with  $13 \leq m \leq 17$ ,  $m < n \leq 29$ ;  $(2, m, n)$ , with  $m \geq 5$ ,  $n \geq 7$ .

## Conclusions (4)

**Remark.** (1) We have worked on the first three classes of signatures. For permutations of  $(2, m, n)$ ,  $m \geq 5$ ,  $n \geq 7$ , the related work will be undertaken in future studies.

(2) We can continue to exclude the multiples of some solved signatures, e.g.,  $(4, 5, 2n)$ ,  $(4, 5, 3n)$ ,  $(4, 5, 5n)$  with  $n \geq 1$ .

### Corollary

To solve the generalized Fermat equation  $x^r + y^s = z^t$  with exponents  $r, s, t \geq 4$ , we are left with 244 signatures  $(r, s, t)$  up to permutation; to solve the Beal conjecture, we are left with 2446 signatures  $(r, s, t)$  up to permutation.
